Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

23 Smith et al. (2024) create a new subspecies of white-tailed deer (*Odocoileus virginianus*)
24 occupying Douglas County, Oregon. The authors should be commended for assembling all
25 available information on the Columbian white-tailed deer (*O. v. leucurus*) to support their
26 argument, unfortunately the authors interpretation of the data is not compelling nor entirely
27 accurate. Their justification for subspecific distinction is based on: 1) a misinterpretation or
28 exclusion of relevant genetic analyses (Hopken et al. 2015; Piaggio et al. 2016; Piaggio and
29 Taylor 2022), 2) an untenable definition of subspecies based on those genetic analyses and on
30 clinal skull morphology of three small, isolated, and fragmented sampling localities.

31

32 **Genetic Data**

33 Mitochondrial Sequence Data

34 Genetic data and historical records tell us subpopulations of Columbian white-tailed deer, (*O. v.*
35 *leucurus*) share a very recent common ancestor and that the anthropogenic actions resulted in
36 population isolation and interrupted gene flow in recent history, likely within the last 100 years
37 (Hopken et al. 2015, Federal Register 81 FR71386 2016-24790). Initial genetic analyses were
38 based on allozymes across 35 genomic loci (Gavin and May 1988), no significant differentiation
39 was detected between deer from Douglas County, Oregon (DCOR) and Lower Columbia River
40 (LC)/Julia Butler Hansen National Wildlife Refuge (JBH). Later mitochondrial DNA (mtDNA)
41 haplotypes from the rapidly evolving hypervariable Region I of the control region (HVI: 614
42 base pairs) were obtained from samples collected from the LC/JBH, DCOR, northeastern OR,
43 southeastern WA, ID, and WY. These largely grouped in a single Clade A (Hopken et al. 2015,
44 figure 2) with a mean sequence divergence of 0.74%. Relationships of the 23 haplotypes within
45 this clade are unresolved as there is very little genetic diversity or genetic distance among

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

46 haplotypes (range 0.163-1.47% sequence divergence). Hopken et al. (2015) recovered only four
47 haplotypes from individuals sampled at LC/JBH (except one that fell into a Columbian black-
48 tailed deer [*O. hemionus columbianus*] clade, denoting introgression between these species at
49 JBH) and DCOR (LC/JBH = 3, DCOR = 1). Hopken et al. (2015, figure 3) was not used in Smith
50 et al. 2024 but is included here (Figure 1). This figure demonstrates that these four *O. v. leucurus*
51 haplotypes are 1-4 base pairs different from one another with haplotype *c* from LC/JBH being
52 only 1 bp different from haplotype *b* in DCOR, but 3 bp different from another haplotype (*a*) in
53 LC/JBH. Further, haplotype *a* from LC/JBH is 2 bp different from the DCOR haplotype (*b*).
54 Remarkably, there is a haplotype of the Northwest white-tailed deer (NWWTD, *O. v. ochrourus*)
55 that is a single bp different from both *a* (LC/JBH) and *b* (DCOR) haplotypes. Earlier work by
56 Cronin (1991) was the first to identify a shared mtDNA haplotype between DCOR, LC/JBH, and
57 NWWTD (haplotype *c*; Cronin 1991). These data clearly illustrate the recent shared ancestry
58 among these haplotypes representing two subspecies (*O. v. ochrourus* and *O. v. leucurus*)
59 including both subpopulations of *O. v. leucurus*. Smith et al. (2024) ignored the fact that the
60 DCOR haplotype they sampled is intermediate among the three haplotypes at LC/JBH and 1 bp
61 different from LC/JBH and NWWTD (Figure 1).

62
63 Smith et al. (2024) based the subspecific distinctiveness on the fact that haplotypes detected in
64 each *O. v. leucurus* subpopulations were not shared. This ignores clear shared ancestry and
65 effects of the process of random mutation and genetic drift in a small population that likely led to
66 the single base change between the haplotypes of *O. v. leucurus* subpopulations and between
67 them and *O. v. ochrourus*. The HVI is often used for infraspecific analyses specifically because
68 of its high mutation rate and phylogenetic resolution (Hasegawa et al. 1993; Wakeley 1993).

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

69 Separating the DCOR population from LC/JBH and those from *O. v. ochrourus* taxonomically
70 creates a paraphyletic relationship among haplotypes that have a mean sequence divergence of
71 $\leq 1\%$ (Hopken et al. 2015).

72
73 We analyzed 36 additional samples collected from LC/JBH during 2016-2021 (Piaggio and
74 Taylor 2022). All but six matched two of the three haplotypes from Hopken et al. (2015) already
75 found in LC/JBH (GenBank Accession # KP308222.1 from Cathlamet, WA, and GenBank
76 Accession # KP308266.1 from Westport, OR). The other 6 individuals had mitochondrial DNA
77 haplotypes that were identical to two haplotypes (GenBank Accession # KP308229.1 and
78 GenBank Accession # KP308236.1) both from Tenasillahe Island (Piaggio and Taylor 2022),
79 that are more closely related to *O. h. columbianus* than to any white-tailed deer samples (Hopken
80 et al. 2015). This apparent introgression of *O. h. columbianus* into *O. v. leucurus* was previously
81 described as an ongoing threat to the genetic diversity of the LC/JBH population which could be
82 exacerbated by isolation from other shared ancestral gene pools (Gavin and May 1988, Cronin
83 1991, Hopken et al. 2015, Piaggio and Taylor 2022). Smith et al. (2024) do not address the
84 potential for these hybrids to be included in their analyses and influence the morphological
85 characteristics they analyze (see below under **Cranial Morphology**).

86
87 **Microsatellites**

88 Piaggio et al. (2016) identified 13 new alleles from LC/JBH in 101 samples collected in 2014
89 and 2015. These samples came from *O. v. leucurus* that were being translocated from LC/JBH to
90 the Ridgefield National Wildlife Refuge (RNWR) and Cottonwood Island, Wahkiakum County,
91 Washington. The USFWS had been translocating Columbia River *O. v. leucurus* among islands

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

92 of the LC/JBH and from both the Oregon and Washington mainland since 1984 to facilitate gene
93 flow (Azerrad 2016) and to increase the number of subpopulations. Of the 13 new alleles
94 identified in the LC/JBH samples, 9 were also seen in either DCOR or *O. v. ochrourus*. One of
95 the new shared alleles between LC/JBH and DCOR was previously documented as a private
96 allele (Hopken et al. 2015) and was used by Smith et al. (2024) to argue for taxonomic
97 distinctiveness for the DCOR subpopulation. However, in a larger analysis (Piaggio & Taylor
98 2022) across 409 samples, allele 192 at locus K, had a frequency of 0.28 in DCOR and 0.007 in
99 LC/JBH (specifically in the mainland WA population), illustrating the difficulty of relying on
100 rare private alleles in small subpopulations as the basis for taxonomic revision. Further, two
101 individuals captured at LC/JBH clustered with the DCOR population, meaning they shared more
102 allelic diversity with DCOR samples than with LC/JBH (Piaggio et al. 2016). This result is not
103 surprising given that in 2010, eight individuals were moved from DCOR to LC/JBH (Azerrad
104 2016) and seven of these were genotyped and included in the analysis (Piaggio et al. 2016). It is
105 also predictable that Piaggio et al. (2016) found new alleles in LC/JBH in the 101 new samples
106 in addition to the 80 samples analyzed by Hopken et al. (2015) because greater sample size
107 increases the chances of detecting rare alleles. Overall, the subpopulations of *O. v. leucurus* do
108 not meet the subspecies definition of Smith et al. (page XX), given they have more shared alleles
109 between them than private ones that separate them. Given the logic in Smith et al. (2024) each
110 population with a private allele at a neutral locus would be candidate for subspecies designation.
111
112 Piaggio and Taylor (2022) further analyzed 409 *O. v. leucurus* individuals and found allele 159
113 at locus BM4208 still a private allele for LC/JBH subpopulation of *O. v. leucurus*, and it was
114 also found across all 5 sampling localities at LC/JBH. Smith et al. (2024) rely on a STRUCTURE

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

115 plot (Figure 4; Figure 6, Hopken and Piaggio 2009; text Hopken et al. 2015) to argue that the
116 LC/JBH and DCOR populations are distinct. However, they state in the text, which is verbatim
117 from Hopken et al. 2015, that there are individuals with shared assignment between LC/JBH and
118 DCOR. More importantly, STRUCTURE plots can appear to show clear differentiation in
119 populations with low genetic diversity because they have different allele frequencies. Thus,
120 further data and interpretation with an understanding of evolutionary processes (such as genetic
121 drift in this case) are required to assess connectivity rather than simply relying on a visual plot
122 (Lawson et al. 2018). Further, there were two genetic clusters within LC/JBH using STRUCTURE
123 (Piaggio and Taylor 2022, figure 2), rather than the single one identified previously (Hopken and
124 Piaggio 2009; Hopken et al. 2015). It is clear, that these two genetic clusters are not isolated
125 breeding populations, but in fact share some gene flow given geographical proximity and known
126 translocation history (Piaggio and Taylor 2022, figure 1). However, given Smith et al.'s
127 subspecific designation of the DCOR subpopulation based on a STRUCTURE plot, these too could
128 be considered separate subspecies.

129

130 *Fst*

131 *Fst* is a metric that describes the reduction of heterozygosity due to genetic drift and thus can
132 identify population subdivision (Hartl 1981). It is used to estimate relative differences between
133 subpopulations but should not be used as a basis for taxonomic revision. In fact, low overall
134 genetic diversity within a population can lead to inflated *Fst* between some genomic regions. If
135 one population has a certain allele, or set of alleles, and another population has a different allele,
136 this does not mean that there is no gene flow or that other regions do not show lower *Fst*
137 (Cruickshank and Hahn 2014). Smith et al. (2024) lean heavily on an oversimplified

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

138 interpretation of F_{st} to describe their new infraspecific designation. F_{st} can be inflated by low
139 genetic diversity (Jost 2008) due to genetic drift and inbreeding. Further, F_{st} between
140 subpopulations of *O. v. leucurus* may be detecting historical isolation-by-distance, which is a
141 common pattern of population structure in white-tailed deer (Cullingham et al. 2011, Bauder et
142 al. 2021, Burbrink et al. 2022). As such, these subpopulation differences are not valid support for
143 a new taxonomic designation for one of the subpopulations.

144
145 The genetic basis for creating a new subspecies consisting of the DCOR subpopulation of *O. v.*
146 *leucurus* as argued by Smith et al. (2024) comes down to the single private allele across the
147 LC/JBH subpopulation, F_{st} values, and a single haplotype that is found in only the DCOR
148 population but is 1 bp different from LC/JBH and northeastern Oregon populations. The
149 alternative and most parsimonious explanation of these patterns is random genetic drift in two
150 subpopulations that were part of larger, historical population but have been isolated by habitat
151 fragmentation resulting in lower genetic diversity and inbreeding.

152

153 **Cranial Morphology**

154 Smith et al. (2024) identified statistically significant morphological differences between *O. v.*
155 *leucurus* and *O. virginianus* from northern Idaho. These differences are primarily related to
156 overall size of the skulls (basilar length, least interorbital breadth, zygomatic breadth, and
157 mastoid breadth), which are subject to strong environmental influences. Smith et al. (2024,
158 figures 1 and 2) show a general body size cline from larger deer in northern Idaho (Bonner
159 County $n = 8$ and Latah County $n = 1$), west into Wahkiakum County, Washington ($n = 24$) and
160 Tenasillahe Island, northern Oregon ($n = 1$), and south into Douglas County in southern Oregon

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.
161 (DCOR, $n = 63$) being the smallest. This sampling scheme is noteworthy given that Bonner
162 County, Idaho, is approximately 500 miles from the next sampling locality, Wahkiakum County,
163 Washington, and about 650 miles from the subpopulation in question in Douglas County,
164 Oregon. Nonetheless, considering there is a well-established clinal size relationship in deer
165 (Heffelfinger and Heffelfinger 2023) it should not be surprising that three small and isolated
166 populations along that cline would show statistically significant differences. It is questionable,
167 however, whether these represent taxonomically relevant differences or simply a difference in
168 nutritional resources available. They also claim that habitat differences between LC/JBH and
169 DCOR "...have imposed selective pressures", however, this is pure speculation as they assume
170 that skull size is completely due to selection but no test for selection or heritability was attempted
171 for these populations.

172
173 Smith et al. (2024, figure 3) describe the results of their principal component analysis as
174 representing "*slightly overlapping groups*", however there is a considerable amount of overlap,
175 likely owing to the recent gene flow of these populations before anthropogenic fragmentation of
176 their habitat. Smith et al. (2024, figure 2B) shows individuals from the LC region overlapping
177 most of the samples from other 2 populations. This overlap is also counter to the ability to
178 diagnose individuals as one of the subspecies because it is based on a test of means rather than a
179 diagnostic trait which limits classification of a future, random individual. One quantifiable
180 definition of subspecies is that 75% of individuals in one subspecies must fall outside 99% of the
181 other (Amadon, 1949, Patten and Unitt 2002). While not all taxonomists accept this definition, it
182 is an attempt to make morphometric measurements diagnosable. A cursory review of the PCA
183 indicates that it appears to violate this 75% rule, thus there are no characters to distinctively

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

184 classify most individuals as DCOR or LC/JBH. In addition, there is a danger of interpreting
185 morphological information without considering the extent of hybridization in these samples. The
186 LC/JBH subpopulation is known to contain individuals with *O. h. columbianus* genes, which
187 may affect some morphological traits. Figure 2B (Smith et al. 2024) contains several outliers
188 from the LC/JBH subpopulation. The uncertainty of the lineage of these samples adds more
189 ambiguity to the reliability of the morphological data. Given the environmental plasticity of
190 skulls independent of phylogenetic descent and potential for hybrids, analyses of a few small and
191 recently isolated deer populations at this regional scale do not provide compelling support for
192 creating a new subspecies of deer that is the *O. v. leucurus* subpopulation from DCOR.

193

194 **Untenable Subspecies Concept**

195 Taxonomic separation of *O. v. douglasi* out of what is now *O. v. leucurus* in Douglas County,
196 Oregon is contrary to conservation community efforts to increase landscape connectivity and
197 pools of genetic diversity of deer populations throughout the western North America (Middleton
198 et al. 2020, Kauffman et al. 2022). The genetic data from *O. v. leucurus* subpopulations support
199 the historical record that they were all part of a regional panmictic population. Over-splitting
200 taxonomic categories can invite activist litigation (Baier 2015), dilute resources available to
201 imperiled taxa, and impede conservation by discouraging translocations and other efforts to
202 foster evolutionarily potential through restoring once shared genetic diversity (Latch and
203 Heffelfinger 2022). Further, introgression of *O. hemionus* genome into *O. v. leucurus* is a threat
204 to the integrity of the unique genetic diversity remaining, given that in small populations rare
205 and/or recessive alleles can become common (Rhymer and Simberloff 1996). Ralls et al. (2018)
206 reviewed the genetic rescue literature and outlined an approach that reduces extinction risk of

Note: This comment has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). *Northwest Science* 97(4): *in press*.

207 isolated populations that were once part of a larger widely distributed species. They determined
208 that populations that are “...chromosomally compatible, were isolated by human activities within
209 the last 500 years and are not adapted to strongly different environments” should be managed in
210 a way to increase genetic diversity rather than maintain isolation. The fact that deer from DCOR
211 have survived and increased the genetic diversity already in the LC/JBH population counters the
212 argument that they are now uniquely adapted to DCOR and demonstrates that the populations are
213 “chromosomally compatible”. The question, as we see it, is whether or not we should allow the
214 separation imposed by anthropomorphic alterations to natural corridors of gene flow to continue
215 to exist and erode genetic diversity. We argue that taxonomic distinction of the *O. v. leucurus*
216 subpopulations is invalid and instead that evolutionary potential of white-tailed deer west of the
217 Cascade mountains would benefit from a restored shared gene pool.

328 **Figure Legend**

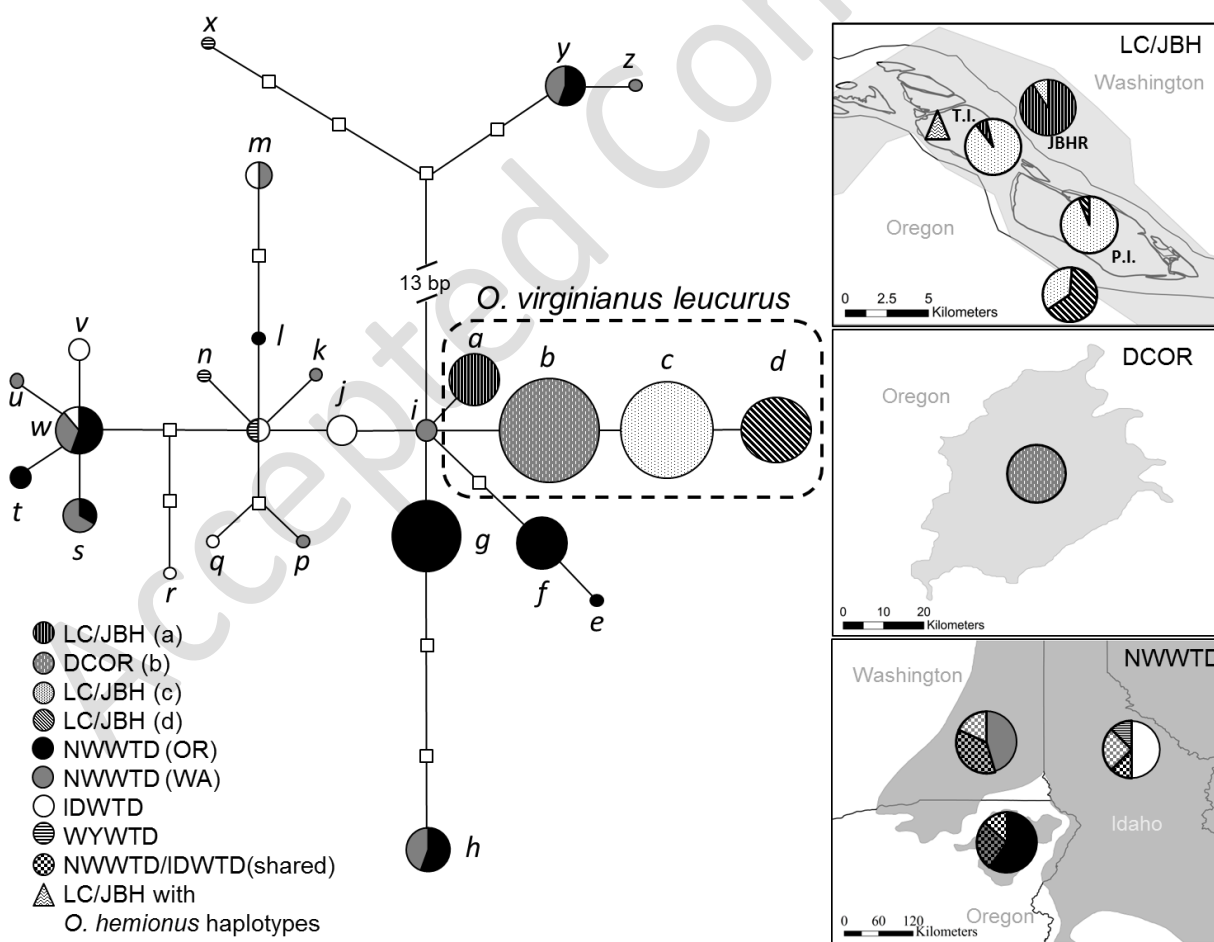

329

330 Figure 1. Median-joining network generated in NETWORK v4.6.1 for 614 base pairs of the
331 mitochondrial DNA control region from *Odocoileus virginianus* collected from the Pacific
332 Northwest, U.S.A. (Hopken et al. 2015, figure 3). Each circle represents a haplotype with the
333 branch in between representing one base pair change. The size of each haplotype circle
334 represents its frequency among all *O. virginianus* samples. The colors and patterns represent a
335 particular sampling location and circles with two or more colors or patterns were found in
336 multiple locations (see legend and insets). The squares represent missing/unsampled/extinct
337 haplotypes. The insets show the location of each haplotype: Lower Columbia River/Julia Butler
338 Hansen Refuge (LC/JBH); Douglas County, Oregon (DCOR); Eastern Oregon (OR); Eastern
339 Washington (WA); Idaho (ID) and Wyoming (WY). Haplotypes found in *O. v. leucurus* are
340 labeled and have designated letters (*a–d*). Note that haplotype *b* from DCOR is intermediate
341 between *a*, *c*, and *d*, all from LC/JBH. Also, that *a* and *b* are one base difference from *i*, which is
342 a NWWTD from WA. Finally, *a* is more closely related to *i* than to other haplotypes from
343 LC/JBH (*c* and *d*). The circles within the insets demonstrate the geographical distribution of the
344 haplotypes (see legend). The checkered pattern haplotypes in the OR, WA, ID inset represent

Piaggio AJ, Heffelfinger JR, Meyers PM, Hopken MW. 2024. Creating an endangered subspecies: a comment on Smith et al. (2024). Northwest Science 97(4): *in press*.

345 haplotypes shared with another location within the inset. For example, a grey/white checkered
 346 pattern means those haplotypes are shared among the locations marked with solid grey and solid
 347 white (see legend). A solid color in the OR, WA, ID inset means that those haplotypes were only
 348 found in that location. The triangle in the LC/JBHR inset represents the collection location of the
 349 *O. v. leucurus* individuals with the *O. h. columbianus* haplotype (Hopken et al. 2015, fig. 2). The
 350 abbreviations in the LC/JBHR inset represent: Julia Butler Hansen NWR Washington mainland
 351 (JBH); Puget Island, WA (P.I.) and Tenasillahe Island, OR (T.I.). Letters at nodes are haplotype
 352 designations and correspond to those in Table A3 (electronic supplementary material Hopken et
 353 al. 2015).
