33 **Abstract**

34

35 We examined the seasonal movements of adult yellow perch (*Perca flavescens*) between a small,  
36 shallow lake (Lake Union) and a large, deep lake (Lake Washington). Lake Union is the largest  
37 part of the Lake Washington Ship Canal (LWSC), a narrow waterway between Lake Washington  
38 and Puget Sound. Yellow perch were implanted with acoustic tags that had a battery life of at  
39 least 460 days. All tagged yellow perch were captured and released in Lake Union in the summer  
40 of 2020 or 2021. Movements were monitored primarily with 14 stationary receivers that were  
41 deployed at key locations between the two lakes. Additional information was obtained from  
42 mobile tracking and other stationary receivers in Lake Washington. Of the 47 fish tagged, we  
43 were able to get seasonal movement data on 28 fish. Twenty-three (82%) of them left Lake  
44 Union and moved into Lake Washington while the other five (18%) remained in the LWSC.  
45 Most movements from Lake Union to Lake Washington occurred in September or October when  
46 water temperatures were decreasing. Return movements from Lake Washington to Lake Union  
47 had variable timing. Migrations between Lake Union and Lake Washington usually took just a  
48 few hours and took place day or night. The farthest observed distance moved from the release  
49 site was approximately 16 km. Within Lake Washington, tagged yellow perch were found over a  
50 broad area in the northern two-thirds of the lake. Overall, tracking results indicated yellow perch  
51 can make extensive migrations between the two lakes.

52

53 **Key points:**

- 54 1) Adult yellow perch from Lake Union were implanted with acoustic tags to monitor their  
55 seasonal and diel movement patterns.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

- 56        2) Most yellow perch left Lake Union in the fall as temperatures were declining and  
57            migrated to Lake Washington where better overwintering conditions are present.
- 58        3) Migrations between Lake Union and Lake Washington usually took just a few hours and  
59            took place day or night.

62 **Introduction**

63

64 Potamodromous fishes of North America often make seasonal reproductive, feeding, and  
65 overwintering migrations (Thurrow 2016). Like other fish migrations, potamodromous migratory  
66 behavior is thought to arise from separation of optimal habitats for growth, survival, and  
67 reproduction (Lucas and Baras 2001). In the Pacific Northwest, seasonal feeding migrations of  
68 piscivorous potamodromous fishes can occur in response to high abundance of migrating  
69 juvenile anadromous salmonids. This can be particularly noticeable near dams, at river mouths,  
70 and after hatchery releases because juvenile salmonids may be concentrated and vulnerable to  
71 predation. An understanding of the movements of these piscivores can help evaluate  
72 management options such as predator suppression efforts, dam operations, and hatchery release  
73 strategies.

74 Yellow perch (*Perca flavescens*) is a widespread introduced species in the Pacific  
75 Northwest, and their range appears to be expanding (McPhail 2007, Runciman and Leaf 2009).  
76 Because they can be abundant and consume a wide variety of prey types including small fishes,  
77 they may have important ecosystem effects (Post and Cucin 1984, Schindler and Carter 2006,  
78 Bradford et al. 2008). Although they are widespread and abundant in the Pacific Northwest, they  
79 have been understudied especially as a potential predator of juvenile salmonids (Schindler and  
80 Carter 2006). High predation rates of juvenile salmonids by yellow perch have been observed in  
81 a few instances (Dahle 1979, Miller 2012, Beck 2013) but most studies have observed little of no  
82 predation (Bonar et al. 2005). Yellow perch are considered secondary piscivores because they  
83 can take years to become piscivorous, are generally slow-moving, and are never more than 30-

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

84 40% piscivorous (Keast 1985). However, even low predation rates of salmonids may still be  
85 important if yellow perch are far more numerous than other predators.

86 Potamodromy in yellow perch is not well known. Reviews of yellow perch biology by  
87 Craig (2000), Lucas and Baras (2001), and Wydoski and Whitney (2003) concluded that annual  
88 distances moved by yellow perch are not extensive and most are localized. Generally, large adult  
89 yellow perch overwinter in offshore deep waters and move into shallow waters in the spring to  
90 spawn and then move farther from shore in the summer to feed (Bartoo 1972, Radabaugh et al.  
91 2010, Feucht et al. 2023). These seasonal inshore/offshore movements can often take place in a  
92 localized area. Also, some yellow perch have relatively small home ranges (Fish and Savitz  
93 1983, Helfman 1984). However, in some locations yellow perch appear to have extensive  
94 migrations. For example, Glover et al. (2008) found some yellow perch in Lake Michigan moved  
95 10 to 40 km during both summer and non-summer months. In an earlier study in Lake Michigan,  
96 the maximum distance moved was 90 km (Smith and Van Oosten 1940).

97 For the most part, adult yellow perch in the warmer months (late spring to early fall) tend  
98 to be active during the day and inactive and rest on the bottom at night (Emery 1973, Helfman  
99 1979, McCarty 1990, Bauer et al. 2009). At dawn, yellow perch move up in the water column  
100 and begin to feed. Some move offshore to feed on zooplankton and small fishes while others  
101 remain in the littoral zone to feed on a mixture of zooplankton and benthic prey (Scott 1955,  
102 McCarty 1990). Peak activity and feeding of yellow perch occurs primarily at dusk (Hasler and  
103 Bardach 1949, Keast and Welsh 1968, Costa 1979). During the day, individual adult yellow  
104 perch are often solitary while others are in schools and thus, they are considered facultative  
105 schoolers (Helfman 1984). Schooling by yellow perch appears to improve foraging efficiency  
106 when preying on small fishes (Nursall 1973). Although, yellow perch are primarily diurnally

Note: This article has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

107 active, there are periods when they may be active at night. Spawning typically takes place during  
108 the night and early morning (Scott and Crossman 1973). Also, during ice conditions, yellow  
109 perch appear to be active at night, but their activity is reduced and are off the bottom and slowly  
110 swimming (Hergenrader and Hasler 1966).

111 In the Lake Washington basin in western Washington State, yellow perch are abundant  
112 and coexist with anadromous salmon populations. High levels of predation of migrating Chinook  
113 salmon (*Oncorhynchus tshawytscha*) by yellow perch has been documented in some widely  
114 separated areas of the Lake Washington basin (R. Tabor, unpublished data). One of these  
115 locations is the north part of Lake Union which is part of the Lake Washington Ship Canal  
116 (LWSC), a narrow-engineered waterway at the downstream end of the basin. Lake Union is a  
117 natural small shallow lake and is roughly 3.5 km from Lake Washington, a large, deep lake  
118 where large numbers of yellow perch are known to be present year-round. Large yellow perch (>  
119 250 mm TL) have commonly been caught in Lake Union in June and July and often prey on  
120 emigrating Chinook salmon smolts during this period. It is unclear if Lake Union yellow perch  
121 represent a separate population from Lake Washington or if they represent a feeding migration  
122 from Lake Washington that could migrate to Lake Union in response to the emigration of  
123 Chinook salmon prey.

124 The overall objective of this study was to document the seasonal movement patterns of  
125 adult yellow perch in Lake Union and determine if they migrate to Lake Washington. Movement  
126 information of yellow perch is needed to help guide possible suppression efforts of this invasive  
127 fish species. Secondly, we were interested in determining if their seasonal migrations overlapped  
128 with emigration of Chinook salmon smolts through the LWSC. Because yellow perch are  
129 abundant and if their movements considerably overlap with Chinook salmon migrations, yellow

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

130 perch have the potential to impact Chinook salmon populations. Lastly, we examined the diel  
131 movement of yellow perch when they moved between Lake Union and Lake Washington. To  
132 address these objectives, adult yellow perch in Lake Union were implanted with acoustic  
133 transmitters and their seasonal and diel movements monitored with stationary receivers.

134

## 135 **Study Area**

136

137 Lake Union and Lake Washington are in the lower portion of the Lake Washington basin, which  
138 is approximately 1,570 km<sup>2</sup>. Lake Union is part of the Lake Washington Ship Canal (LWSC)  
139 which is a 10.8-km-long, narrow waterway that allows navigation between Lake Washington and  
140 Shilshole Bay in Puget Sound (Figure 1). The LWSC consists of five sections: Montlake Cut,  
141 Portage Bay, Lake Union, Fremont Cut, and the Salmon Bay waterway. The Fremont Cut and  
142 Montlake Cut of the LWSC are narrow channels with steep armored banks. Shorelines of the rest  
143 of the LWSC are highly developed and contain numerous marinas, commercial shipyards, and  
144 house-boat communities. The Ballard Locks located at the downstream end of the LWSC  
145 controls the water level of the LWSC and Lake Washington. Originally, Lake Union and Lake  
146 Washington were not connected. The LWSC and Ballard Locks were constructed in 1910-1920.  
147 Prior to construction of the LWSC, Lake Washington drained south to the Black and Duwamish  
148 rivers. A ridge separated Union Bay from Portage Bay and a small stream drained Lake Union  
149 into a tidally influenced Salmon Bay.

150 The largest part of the LWSC is Lake Union, which is 235 ha in size, has a mean depth of  
151 10.5 m and maximum depth 16 m. Lake Union is a warm, monomictic lake that stratifies in  
152 summer. Surface water temperatures commonly exceed 21°C. Water clarity is typically lower in

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

153 Lake Union than Lake Washington during the summer months (Celedonia et al. 2008). Saltwater  
154 typically intrudes into Lake Union every summer as lockages at the Ballard Locks increase and  
155 discharge levels decrease (King County 2018). The magnitude and duration of the intrusion  
156 varies from year to year but generally affects the area of the lake below 10 m depth. Besides  
157 elevated salinity, this deep area has increased temperature, sustained anoxia, and depressed pH  
158 (King County 2018). Montlake Cut, Portage Bay, and Fremont Cut have a mean depth of 9-11 m  
159 to allow for navigation of large vessels.

160 Upstream of the LWSC is Lake Washington, a large monomictic lake with a total surface  
161 area of 8,900 ha, mean depth of 33 m, and a maximum depth of 65 m. The lake typically  
162 stratifies from May to early November with a thermocline around 16 m. Surface water  
163 temperatures range from 6-7°C in winter to over 20°C in summer. The lake appears to have  
164 sufficient dissolved oxygen levels even in the deepest parts of the lake to support  
165 macroinvertebrate and fish communities (Thut 1969, Tabor et al. 2007). Over 78% of the  
166 shoreline is comprised of residential land use (Toft 2001).

167 The Lake Washington basin is inhabited by a relatively large number of fish species,  
168 including 25 native species (primarily salmonids, cottids [*Cottus* spp.], and cyprinids) and at  
169 least 20 introduced species. The history of yellow perch planting in the Lake Washington  
170 system is not clear, but they may have been present since the early 1900s (Lampman 1946).  
171 Yellow perch appear to be the most abundant of the introduced fish species in Lake Washington  
172 (Garrett et al. 2017). Anadromous salmonids in the Lake Washington system are comprised  
173 primarily of sockeye salmon (*O. nerka*), Chinook salmon, and coho salmon (*O. kisutch*). The  
174 Chinook salmon population is part of the Puget Sound Evolutionarily Significant Unit that is  
175 currently listed as threatened under the Endangered Species Act (ESA; Federal Register 64 FR

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

176 14208, March 24, 1999). Chinook salmon in the Lake Washington system outmigrate through  
177 the LWSC as subyearlings from late May through mid-July (DeVries et al. 2004) and may be  
178 particularly vulnerable to predation from predatory fishes such as yellow perch. Within the  
179 LWSC, Chinook salmon smolts typically move through most sections (e.g., Portage Bay and  
180 Fremont Cut) in less than 24 hours; however, in Lake Union, they spend one day to two weeks  
181 (Celedonia et al. 2011). Predation of Chinook salmon smolts by yellow perch in the LWSC has  
182 predominantly been documented in Lake Union with little predation observed in other sections  
183 (R. Tabor, unpublished data).

184

## 185 **Methods**

186

187 We used acoustic telemetry to determine the seasonal movements of Lake Union yellow perch.  
188 They were collected primarily through angling; however, a few were collected with gill nets  
189 (short sets of approximately 15 min). All collection efforts were conducted in north Lake Union;  
190 an area of the LWSC where large yellow perch were known to be common. After capture, fish  
191 were placed in a cooler and transported to a nearby tagging location. All tags were implanted  
192 surgically (Liedtke et al. 2012). All surgical instruments and tags were allowed to soak in a  
193 mixture of 2% Chlorhexidine disinfectant and sterile deionized water for at least 5 min and then  
194 rinsed in a 0.9% sterile saline bath immediately before implantation. Fish were anesthetized and  
195 then measured for total length (TL) and weighed (g). An incision approximately 10–20 mm long  
196 was made on the ventral side between the pectoral and pelvic fins. An acoustic tag was then  
197 inserted into the peritoneal cavity through the incision. Two or three sutures were used to close  
198 the incision. Fish were then placed in a recovery tank of fresh water. The entire operation was

Note: This article has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

199 usually completed in 3–6 min. Fish were allowed to recover for 30-90 minutes before being  
200 released within 100 m of their capture location. A total of 47 yellow perch (mean TL = 245.3  
201 mm; range 221–296 mm TL) were captured, implanted with acoustic tags, and released in the  
202 Lake Union (Figure 1). Twenty fish were tagged in 2020 (July–August) and 27 in 2021 (July).  
203 We used coded V9 Vemco tags that were each programmed to emit a unique identification signal  
204 at random intervals set at 80–200 seconds. All tags were on the same frequency: 69.0 kHz. The  
205 tag weight (4.7 g) was less than 3.2% of the body weight. Tag battery life was expected to be at  
206 least 460 days. Some tags had detections over 550 days after release.

207         Movements of tagged fish were primarily monitored with fixed receivers from July 2020  
208 to December 2022. A total of 14 fixed Vemco VR2 receivers were deployed; nine in the LWSC,  
209 two at the west end of Union Bay (transition area between Lake Washington and the LWSC),  
210 and three in Lake Washington at the east end of Union Bay (Figure 1). Receivers provided  
211 presence/absence information and based on range tests they could typically detect tags within  
212 300–500 m. Receivers were primarily placed in narrow gaps of the LWSC where detection  
213 probabilities would be higher. Except for the west end of Fremont Cut, we placed a receiver on  
214 both the north and south side of the LWSC to reduce the likelihood of a tagged yellow perch  
215 moving by without being detected. At each of these pairs of receivers, tags could be detected by  
216 both receivers at the same time depending on fish location; however, simultaneous detections  
217 between pairs of receivers were rare. Of the tagged yellow perch detected in Lake Washington,  
218 all were detected on multiple receivers in the LWSC.

219         To evaluate whether yellow perch from the LWSC were concentrated in one area of Lake  
220 Washington or occur over a broad area, we also collected some additional information from  
221 other stationary receivers as well as mobile tracking. The other stationary receivers consisted of

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

222 nine receivers deployed around Lake Washington by the Muckleshoot Indian Tribe (October  
223 2020 to May 2021) to track walleye (*Sander vitreus*) and adult anadromous salmon  
224 (*Oncorhynchus* spp.). We periodically conducted mobile surveys in Lake Washington along the  
225 central west shoreline from Sand Point to I-90 Bridge (Figure 1). We chose this shoreline  
226 because it was relatively close to the LWSC and we could conduct a survey within one day. We  
227 slowly boated along the shoreline (approximately 30 m from shore) of Lake Washington. The  
228 boat location was used as the approximate location of the fish. The mobile tracking system had a  
229 listening range of approximately 300 m. Mobile surveys were primarily conducted in the late fall  
230 and winter when yellow perch typically aggregate in deeper water. Altogether, four surveys were  
231 conducted, two in 2021 and two in 2022.

232 We evaluated tracking information for each fish and categorized their seasonal  
233 movements as either 1) resident fish that remained in Lake Union and other parts of the LWSC;  
234 2) left Lake Union and moved into Lake Washington; 3) not enough data to determine their  
235 seasonal movement; or 4) fish died or tag was expelled (tag appeared to remain in one location  
236 over an extended period of time). Resident fish were defined as fish that remained in the LWSC  
237 throughout the summer and were still present on September 15 (approximate date when water  
238 temperature at 4 m depth decreases to  $< 20^{\circ}\text{C}$ ). To associate movements with changes in water  
239 temperatures, we deployed two temperature loggers (Hobo Tidbit model UTBI-001, Onset  
240 Computer Corporation, Bourne, MA) with one of our north Lake Union receivers. Loggers were  
241 deployed at 4-m depth. We chose this depth to be roughly the middle of the littoral zone. Yellow  
242 perch are typically found in the littoral zone during the spring and summer.

243 To help understand the movement pattern between the two lakes, we also calculated the  
244 numbers of hours to move between the two lakes by using the first or last detection (depending

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

245 on direction moving) at I-5 Bridge receiver to first or last detection at Webster Point receiver.

246 After accounting for the tag detection range, the distance between these two locations was

247 roughly 2.5 km. To categorize movements between the two lakes as either day, night, or both, we

248 used civil twilight time as the approximate time between day and night. We tested the effect of

249 fish size at tagging on migratory pattern (migrated to Lake Washington versus remained in

250 LWSC) and survival (category 1 and 2 versus category 3 and 4) by using Mann-Whitney *U* tests.

251 Also, we tested size at tagging on date of migration to Lake Washington with a linear regression.

252

## 253 **Results**

254

255 We obtained seasonal movement data on 28 of the 47 tagged yellow perch (Table 1). Eleven of

256 the other fish were detected from 4 to 45 days after tagging but were not detected or only

257 detected once after September 15 and their seasonal movement pattern was not determined. We

258 assumed these fish were removed by anglers or possibly birds (predators or scavengers). Eight

259 tags never moved, and we assumed the fish died or expelled their tag. Size at tagging of yellow

260 perch was similar between those that did not survive ( $n = 19$ ; median length, 240 mm TL) to

261 those that survived ( $n = 28$ , median length, 243.5 mm TL; Mann-Whitney *U* test;  $Z = 1.11$ ;  $P =$

262 0.27). Of the remaining 28 fish, 23 (82%) left the LWSC and moved into Lake Washington and 5

263 (18%) remained in the LWSC and appeared to overwinter there (Figure 2). Migration to Lake

264 Washington was the predominant pattern for both tagging years; 81.9% (9 of 11) for the 2020 tag

265 group and 82.4% (14 of 17) for the 2021 tag group. Of the 23 fish that moved to Lake

266 Washington, two returned to Lake Union within a few weeks and appeared to overwinter there,

267 eight overwintered in Lake Washington and returned to Lake Union the following late winter or

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

268 spring, and the rest were only detected in Lake Washington after leaving the LWSC (Figure 2).  
269 A total of 32 movements (including some fish that moved more than once) from the LWSC to  
270 the lake were recorded. Seventy-eight percent (25 of 32) of these movements were in September  
271 or October (Figure 3) when water temperatures were decreasing (Figure 4). Timing of migrations  
272 back to the LWSC ( $n = 16$ ) was variable but 44% occurred from March to May. Size at tagging  
273 of yellow perch was similar between those that remained in the LWSC ( $n = 5$ ; median length,  
274 243 mm TL; SD = 14.7) to those that migrated to Lake Washington ( $n = 23$ , median length, 244  
275 mm TL; SD = 12.5; Mann-Whitney  $U$  test;  $Z = 0.03$ ;  $P = 0.98$ ). Also, there was no apparent  
276 effect of size at tagging on date of migration to Lake Washington (linear regression;  $r^2 = 0.008$ )

277 Movements between Lake Union and Lake Washington appeared to take a few hours, and  
278 time spent in Portage Bay, Montlake Cut, and east Union Bay appeared to be minimal. For  
279 movements from Lake Union to Lake Washington, the median time from the last detection at I-5  
280 Bridge to first detection at Webster Point (roughly 2.5 km) was 3.85 hours ( $n = 32$ ; range 0.82 to  
281 46.4 hours). For movements from Lake Washington to Lake Union, the median time from the  
282 last detection at Webster Point to first detection at I-5 Bridge was 3.23 hours ( $n = 16$ ; range 0.33  
283 to 21.88 hours). Additionally, some movements between Lake Union and north Lake  
284 Washington were rapid. One tagged fish moved from St. Edwards Park in north Lake  
285 Washington to north Lake Union (approximately 14.5 km) in 50 hours, and this same fish moved  
286 from Lake Union to St. Edwards Park and back to Lake Union in 9 days (Table 2).

287 Movements between Lake Union and Lake Washington (last detection at I-5 Bridge to  
288 first detection at Webster Point and vice versa) occurred both day and night. Of the 48  
289 movements, 16 were daylight only movements, 12 were nighttime only movements, 4  
290 commenced during the daylight and ended that night, 13 commenced at night and ended during

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

291 daylight hours, and 3 extended across more than two diel periods. Of the late summer-fall  
292 migrations (August–November;  $n = 36$ ), 25% occurred just during the day, 28% completely at  
293 night, and 47% both day and night. For the winter and spring combined (December–May;  $n =$   
294 12), 58% occurred just during the day, 17% completely at night, and 25% both day and night  
295 (Figure 5).

296 Within Lake Washington, tagged yellow perch from the first-year releases were found  
297 over a broad area from St. Edwards Park in the north end to the north part of Mercer Island  
298 (Figure 1). When supplemental Lake Washington stationary receivers were operating (October  
299 2020 to May 2021), three were detected north of Mercer Island, two at both St. Edwards and  
300 Sand Point receivers, and no detections were made on the south Lake Washington receivers. The  
301 farthest distance moved from the release site was approximately 16 km by two fish that migrated  
302 to St. Edwards Park in north Lake Washington. The range of mobile tracking detections from the  
303 second-year releases encompassed much of the survey distance (approximately 80%) from I-90  
304 Bridge to Sand Point (Figure 1). Of these eight yellow perch, five were detected south of SR 520  
305 bridge and three north of the bridge.

306

## 307 **Discussion**

308

309 Most yellow perch tagged in Lake Union migrated to Lake Washington. However, roughly a  
310 fifth of them remained in Lake Union and the LWSC and did not migrate to Lake Washington.  
311 Thus, there appears to be large variability among individuals on their seasonal movement  
312 patterns between the two lakes. Additionally, those that did migrate to Lake Washington were  
313 spread out over a large area and the distance migrated varied widely. Other studies of yellow

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

314 perch movements have also found large variability among individuals. Mark-recapture studies of  
315 yellow perch have often found most of the recaptures are close to the tagging site, but some  
316 moved a considerable distance (Mraz 1952, Clady 1977, Glover et al. 2008). Lucchesi (1988)  
317 found there were discrete stocks in Lake Huron that returned to the same area to spawn but their  
318 movements away from the spawning area varied widely. At two sites, most fish were recaptured  
319 close to the original tag and release sites while at a third site, recaptures were over a large area.  
320 Lucas and Baras (2001) concluded that yellow perch do not exhibit substantial movements in  
321 most cases, but they may exhibit longer migrations where habitats for specific conditions are  
322 widely separated.

323 For most yellow perch that inhabit Lake Union during the summer, their summer  
324 foraging location may be Lake Union, but their overwinter location may be Lake Washington  
325 and thus, they undergo extensive migrations between the two water bodies. Migrations to Lake  
326 Washington primarily occurred in September and October with declining water temperatures. As  
327 water temperatures drop in the fall, yellow perch often move to deep overwinter locations  
328 (Reigle 1969, Schaefer 1977) and often inhabit the deepest parts of a lake during the winter  
329 (Becker 1983). Bartoo (1972) found yellow perch in Lake Washington in deep areas around 18  
330 m. Also, large numbers of yellow perch were collected in Lake Washington during the winter  
331 with offshore bottom trawls (30–50 m deep; E. Warner, unpublished data). The maximum depth  
332 of Lake Union is only 16 m and water quality below 10 m depth may limit yellow perch use due  
333 to elevated salinity, low dissolved oxygen, and depressed pH (King County 2018). Water quality  
334 conditions during the winter in these deep areas of Lake Union can vary widely from year to  
335 year. In other systems, yellow perch have also shown a strong movement to overwinter sites. In a  
336 similar situation in two Iowa lakes, yellow perch moved from a shallow lake to an adjoining

Note: This article has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

337 deep lake to overwinter (Schmitt and Hubert 1983). Also, yellow perch moved downstream out  
338 of Big Garlic River to Lake Superior in September and October as water temperatures decreased,  
339 presumably to overwinter (Manion 1977).

340 Movements back to Lake Union from Lake Washington were highly variable and may be  
341 related to various factors such as spawning and prey availability. Some occurred in the fall by  
342 fish that made multiple trips between the two lakes, and these migrations may have been related  
343 to locating suitable overwintering sites. Radabaugh et al. (2010) also found yellow perch  
344 movements were highest in the fall in an Iowa lake. A few of the movements we observed were  
345 in March and April which may have related to spawning. Yellow perch typically spawn in April  
346 in Lake Washington but the extent and timing of spawning in Lake Union and the LWSC is  
347 unknown. Also, there is some evidence that yellow perch home to the same spawning site year  
348 after year (Clady 1977, Lucchesi 1988), thus these may be returning to Lake Union to spawn  
349 after overwintering in Lake Washington. Post-spawning migrations in April and May may have  
350 also been related to prey availability. Major prey items of adult yellow perch in Lake Union and  
351 Lake Washington during the spring include threespine stickleback (*Gasterosteus aculeatus*;  
352 primarily eggs but also adult fish), sculpin (*Cottus* spp.), Chinook salmon smolts, longfin smelt  
353 (*Spirinchus thaleichthys*), zooplankton, and benthic invertebrates (Overman et al. 2009, R.  
354 Tabor, unpublished data). and the relative abundances and distributions of these prey items might  
355 influence movements to Lake Union. For example, yellow perch may follow the migrations of  
356 Chinook salmon smolts as the smolts emigrate from Lake Washington through the LWSC to  
357 Puget Sound. Abundances of threespine stickleback and longfin smelt vary widely from year to  
358 year (Moulton 1974, Peter Lisi, Washington Department of Fish and Wildlife, unpublished data)  
359 and yellow perch movements patterns may also vary in response to changes in prey availability.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

360 Movement patterns and distribution of yellow perch in the LWSC often overlap with  
361 Chinook salmon smolts. These smolts migrate through the LWSC from late May through mid-  
362 July (DeVries et al. 2004), which is the same period when many yellow perch would be present  
363 in Lake Union. Within the LWSC, large yellow perch are predominately found in north Lake  
364 Union (Garrett et al. 2018), which is the same area where Chinook salmon spend most of their  
365 time while they are in the LWSC (Celedonia et al. 2011). Thus, there is substantial temporal and  
366 spatial overlap between the two species. However, it is unclear how much of yellow perch's  
367 behavior is in response to Chinook salmon smolts migrations. Chinook salmon comprises  
368 roughly 20% of the diet (mean proportion by weight) of yellow perch > 250 mm TL (R. Tabor,  
369 unpublished data). Perhaps there are also some other environmental conditions (e.g., habitat and  
370 prey availability) that attract large yellow perch to Lake Union. Another location where large  
371 yellow perch aggregate and prey on Chinook salmon smolts is Webster Point (R. Tabor,  
372 unpublished data). At both Lake Union and Webster Point, water currents change direction  
373 around a point and yellow perch may be able to take advantage of migrating or drifting prey  
374 more easily. In Lake Mendota, Wisconsin, yellow perch were attracted to areas near a point  
375 where *Daphnia* had accumulated (Hasler and Bardach 1949).

376 Migrations between Lake Union and Lake Washington usually just took a few hours.  
377 Based on the prolonged swimming performance of yellow perch calculated by Nelson (1989), we  
378 estimated that a 100 g individual could migrate the 2.5 km between our I-5 Bridge and Webster  
379 Point receivers in 1.8 h. Our tagged yellow perch averaged 194 g at time of tagging and would be  
380 expected to swim somewhat faster. The median time we observed between these two points was  
381 3.85 hours. However, yellow perch may not have taken a direct route and may have rested or

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

382 foraged. Overall, it does appear adult yellow perch moved rather quickly between Lake Union  
383 and Lake Washington.

384 To migrate between the two lakes, yellow perch must pass through Portage Bay,  
385 Montlake Cut, and the west part of Union Bay but do not appear to spend much time in these  
386 areas. Recent sampling efforts with variable-mesh gill nets in Portage Bay and the west part of  
387 Union Bay have caught yellow perch but most are relatively small (i.e., < 225 mm TL; Garrett et  
388 al. 2018). It appears large yellow perch only use this area as a migratory corridor. It is unclear  
389 why this area is not used more extensively. Perhaps because it is shallower than Lake Union or  
390 Lake Washington, or perhaps prey availability is lower. The south part of Portage Bay and much  
391 of Union Bay have extensive macrophyte beds which may limit available habitat. Chinook  
392 salmon smolts, an important prey item in May and June, also appear to migrate quickly through  
393 Union Bay and Portage Bay and spend considerably more time in Lake Union (Celedonia et al.  
394 2011); however, this would only explain a small percentage of the yellow perch movements  
395 between Lake Union and Lake Washington. The relative abundance of other important prey  
396 items among different sections of the LWSC is not known.

397 Because yellow perch are considered to be diurnally active and rest on the bottom at  
398 night (Emery 1973, Helfman 1979, McCarty 1990), we expected migrations between Lake  
399 Union and Lake Washington to occur during the day. Instead, we found their movements  
400 occurred during both day and night. For many fish species, activity patterns can breakdown  
401 during migration due to an increase in predation risk (Reebs 2002). Adult yellow perch may be at  
402 risk from large cutthroat trout (*O. clarkii*) and large northern pikeminnow (*Ptychocheilus*  
403 *oregonensis*) but these fishes are uncommon in the LWSC (Garrett et al. 2018) and the overall  
404 predation risk for adult yellow perch is expected to be low. Diel activity patterns may also be

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

405 influenced by season. Although our sample sizes were small, the percentage of yellow perch that  
406 migrated at least partially at night was higher in the fall (September-November) than during  
407 other times of the year. Switching from being diurnally active in the summer to being nocturnal  
408 has been observed in other temperate freshwater fish species (Reebs 2002) and thus yellow perch  
409 may switch to being more nocturnal as temperatures decrease in the fall and winter. Activity  
410 patterns of yellow perch in the LWSC and Lake Washington may also be quite different than  
411 other lakes because the LWSC migration corridor is in a highly urbanized area and has increased  
412 levels of artificial light at night (ALAN) which may allow yellow perch to be more active at  
413 night than in other systems. A higher percentage of movements at night during the fall compared  
414 to other seasons may have also been due to ALAN because these yellow perch would have  
415 started their migration in Lake Union where ALAN is more prevalent than in Lake Washington.  
416 Migration of Chinook salmon smolts in the LWSC has been shown to be impacted by ALAN  
417 (Celedonia et al. 2011). Some piscivorous fishes have also been shown to be more active at night  
418 with elevated ALAN (Becker et al. 2013, Nelson et al. 2021). Czarnecka et al. (2019) also found  
419 elevated levels of ALAN increased the feeding activity of the closely related Eurasian perch (*P.*  
420 *fluviatilis*) but its effect on the diel migration patterns of this species or yellow perch is unknown.

421 An important objective of this study was to provide information on yellow perch  
422 distribution to help guide possible suppression efforts and consequently reduce predation of  
423 Chinook salmon smolts. In Lake Union, suppression efforts would need to occur between May  
424 and September when yellow perch are more abundant. Yellow perch are often targeted by  
425 anglers in Lake Washington and Lake Sammamish in late fall and winter because yellow perch  
426 are in large aggregations. Similar angling efforts would likely be unproductive in Lake Union.  
427 Our tagged yellow perch from Lake Union were found over a broad area in Lake Washington

Note: This article has been peer reviewed and accepted for publication in *Northwest Science*. Copy-editing may lead to differences between this version and the final published version.

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

428 and thus we were unable to identify primary locations where they overwintered and could be  
429 targeted. Additional tracking or hydroacoustic surveys are needed in Lake Washington to  
430 identify these primary locations where yellow perch aggregate and could be targeted.

431 In conclusion, large yellow perch appear to commonly migrate between Lake Union and  
432 Lake Washington. Most leave Lake Union in the fall as water temperatures are declining. Yellow  
433 perch likely migrate to Lake Washington where more favorable overwintering conditions such as  
434 deep water (i.e., > 15 m deep) habitats are present. Lake Washington is substantially deeper than  
435 Lake Union and water quality in Lake Union below 10 m depth can be poor. Timing of yellow  
436 perch movements from Lake Washington to Lake Union were not consistent; however, most  
437 migrations were between January to May, which may be related to either spawning or feeding.

438

#### 439 **Acknowledgements**

440 This project was funded in part from grants by King County Cooperative Watershed  
441 Management (award number 4.8.20.016) and WRIA 8 Salmon Recovery Council. We wish to  
442 thank U.S. Fish and Wildlife Service (USFWS) employees (including Olivia Williams, Greg  
443 Byford, Keith Sweeney, Michael Elam, Marc Solano, Eric Klingberg, Hannah Ferwerda, Suzena  
444 Arias), Washington Department of Fish and Wildlife employees (Joe Short, George Chapman,  
445 Alanna Sutton, Katherine Gordon), Muckleshoot Indian Tribe employees (Eva Fuller, Jesse  
446 Nitz), Tom Friedman, and John Reese for their assistance with the field work. Suggestions by  
447 Regan McNatt and Benjamin Cross (USFWS) and three anonymous reviewers greatly improved  
448 an earlier version of this manuscript. We greatly appreciate all the assistance from the Seattle  
449 Harbor Patrol staff. The findings and conclusions in this report are those of the authors and do  
450 not necessarily represent the views of USFWS.

613

614 Figure 1. Map of Lake Union and Lake Washington including other sections of the Lake  
615 Washington Ship Canal. Fixed receiver locations are shown: USFWS (U.S. Fish and Wildlife  
616 Service, solid diamonds) and MIT (Muckleshoot Indian Tribe, solid squares). Release site in  
617 north Lake Union is indicated with a star. Locations where tagged yellow perch were detected  
618 with mobile tracking equipment is also shown (open circles). Mobile tracking (dashed line) only  
619 occurred along the west shore of Lake Washington from I-90 Bridge to Sand Point.

620

621 Figure 2. Weekly presence data of tagged yellow perch from three areas of the lower Lake  
622 Washington system, June 2020 – November 2022. Lake Union area includes Lake Union, east  
623 Fremont Cut and west Portage Bay; Montlake Cut area includes east Portage Bay, Montlake Cut,  
624 and west Union Bay. All detections from stationary hydrophones and mobile tracking were  
625 included. Vertical lines indicate the release time (left lines) and expected end of tag life (right  
626 lines). Shaded areas indicate period (late May-mid July) when Chinook smolts would be  
627 expected to be migrating through the LWSC. Figure only includes the 28 tagged yellow perch  
628 that we were able to get seasonal movement data. Fish numbers correspond to fish numbers in  
629 Table 1.

630

631 Figure 3. Monthly percent of all yellow perch migrations between the Lake Union (LU) and  
632 Lake Washington (LW). Results are from 23 tagged fish that were tagged in Lake Union (July–  
633 August 2020 and July 2021) and migrated between Lake Union and Lake Washington; n = the  
634 number of all movements between the two water bodies; some fish undertook more than one

Tabor RA, Lantz DW, Urgenson LS, Bosworth A, Warner EJ, Johnson JR. 2024. Seasonal and diel movements of adult yellow perch between two contrasting lakes (Lake Union and Lake Washington) in the Seattle metropolitan area. *Northwest Science* 98(1): *in press*.

635 migration. Five additional fish were tagged in Lake Union but did not migrate to Lake  
636 Washington.

637

638 Figure 4. Mean daily temperatures in north Lake Union at 4-m depth (solid line) and  
639 temperatures at that site (symbols) when yellow perch migrated between Lake Union (LU) and  
640 Lake Washington (LW), July 2020 to December 2022. Solid symbols represent Lake Union to  
641 Lake Washington movements and open symbols represent Lake Washington to Lake Union  
642 movements. Different symbols were used for the two release groups (July-August 2020 and July  
643 2021). Overlapping values were offset slightly for graphical purposes. No temperature data was  
644 available from November 11, 2020 to February 21, 2021.

645

646 Figure 5. Percent of yellow perch movements between Lake Union and Lake Washington that  
647 occurred in different diel categories, July 2020-November 2022. Diel categories: D only =  
648 occurred during the day, N only occurred at night, D / N = commenced during the daylight and  
649 ended that night, N / D = commenced at night and ended during daylight hours, D to D =  
650 commenced during the daylight and extended until daylight hours of the next day, N to N =  
651 commenced at night and extended until the next night. n = the number of all movements between  
652 the two water bodies; some fish undertook more than one migration.

653 **Tables**

654

655 Table 1. Tagging and detection information of yellow perch implanted with acoustic tags from  
 656 Lake Union, July 2020-November 2022. Table only includes the 28 tagged yellow perch that we  
 657 were able to get seasonal movement data. Yellow perch were caught and released on the same  
 658 day. TL = total length. Tagged yellow perch with seasonal movement data were put into two  
 659 categories: 1) resident fish that remained in Lake Union and other parts of the LWSC, or 2) left  
 660 Lake Union and moved into Lake Washington. Detection information is from 14 stationary  
 661 receivers located in the LWSC and in Lake Washington at the east end of Union Bay.

Fish number	Tag number	Release date	TL (mm)	Category	Number of detections	Number of days detected	Last detection		Days from release
